20. ABSTRACT (Continue on reverse side if necessary and identify by block number) This is the fourth in a series of reports designed to provide a guide to the occurrence of atmospheric dust over selected geographical areas. Tabular data on the duration and on the diurnal and monthly variations in the probability of occurrence of blowing dust (visibility less than 11 km) and of dust storms (visibility less than 1 km) are presented for 45 stations which averaged at least 3.7 days per year (1%) with blowing dust. The 45 stations were geographically distributed as follows:		

19. KEY WORDS (cont)

South Korea
Peru
Spanish Sahara
Venezuela

20. ABSTRACT (cont)

Angola (2), Australia (1), China (1), Italy (1), Mali (13), Mauritania (11), Mexico (4), Niger (5), North Korea (1), Peru (2), South Korea (1), Spanish Sahara (2), and Venezuela (1). For 257 stations (in 35 countries) which averaged less than 3.7 days per year with blowing dust, tabular dust data are limited to the mean annual number of days with blowing dust and dust storms.

PREFACE

The authors thank SGT Robert Carroll, Jr., for his assistance in compiling these data and Wendell Watkins for his helpful suggestions during the preparation of this report.

INTRODUCTION

Airborne dust (and sand) is one of the most damaging environmental elements. A dusty atmosphere may contribute to the deterioration of materials and can present serious problems in the operation and maintenance of mechanical and electrical equipment. Moreover, atmospheric dust is a limiting factor in the propagation of electromagnetic energy through the atmosphere.

The primary purpose of this series of reports is to provide a guide to the occurrence of atmospheric dust over selected geographical areas. Part I presented data from two stations in the White Sands Missile Range, New Mexico, area [1]. Part II summarized data on the occurrence of dust at 135 stations in the Middle East, Near East, and North Africa [2]. Part III summarized data on the occurrence of dust at 214 stations in Russia [3]. The purpose of Part IV is to complete the coverage with occurrence data for an additional 302 stations from widely scattered geographical areas.

In Part IV the 302 stations are divided into two categories: those experiencing visibility restrictions by airborne dust at the 1% and greater level (at least 3.7 days per year) and those at less than the 1% level (including 73 stations having no observations of visibility restrictions by airborne dust). For the 45 stations in the former category, individual tables provide the average diurnal variation by month of the likelihood of dust-restricted visibility and average duration factors representing the likelihood of dust-restricted visibility lasting at least 1, 3, 6, 9, 12, and 24 hours. The period of record for these 45 stations had to be at least five years. For the 257 stations at the less than 1% level, a single tabular summary covers the mean annual number of days with dust storms and blowing dust. Stations in this category did not have to meet the five-year requirement.

DEFINITIONS

BLOWING DUST: Dust raised by the wind to moderate heights above the ground and restricting horizontal visibility to less than 7 miles* (11 km).

DUST STORM (including severe): The same as blowing dust, except visibility is reduced to less than 5/8 mile* (1 km).

NUMBER (N) OF DUST OCCURRENCES: The arithmetic mean of the annual number of occurrences of dust equal to or greater than 1 hour duration.

*Federal Meteorological Handbook No. 1, Surface Observations, Change 3, 1 Jul 75.

BACKGROUND

Questions arise on the likelihood of blowing dust or dust storms occurring at a specific time of day and/or month of the year and on the likelihood of their lasting for a specified period of time. In response to a request from the Atmospheric Sciences Laboratory (ASL), White Sands Missile Range, NM, The United States Air Force, Air Weather Service [Environmental Technical Applications Center (ETAC)] tailored an analysis of available magnetic tape records of three hourly (i.e., a single observation taken every 3 hours) weather observations from 651 worldwide stations to answer these questions.

GEOGRAPHICAL COVERAGE

Part IV covers 302 stations. The geographical distribution of these stations is indicated in Figures 1-6. The latitude, longitude, elevation, and World Meteorological Organization (WMO) number for each station are listed in Tables 1-4.

OCCURRENCE

More than 3.7 Days Per Year with Blowing Dust

The data on the variability of the occurrence of dust at each of the 45 stations are contained in Tables 5 through 49. Each table consists of two parts. One part gives the diurnal variation of the occurrence of each of the two visibility classes (less than 1 km and less than 11 km) by month. The percentages represent averages for the period of record and are based on data actually taken at the specified hours. The second part contains the duration factor, in decimal percent, of visibilities reduced to less than 1 km and less than 11 km for periods greater than or equal to 1, 3, 6, 9, 12, and 24 hours.* To find the percent likelihood of a given visibility condition lasting for a certain period of time at a specified hour and month at a specific site, multiply the duration factor by the occurrence. For example, the likelihood of the visibility being less than 11 km for at least 9 hours beginning at 0500 LST in April at Khotan, China (Table 39), is approximately 25 percent (0.50 X 50 percent).

*The original data was acquired at intervals of 3 hours. Thus, a given dust condition which lasted 3 hours or more would be recorded at least once and dust-restricted visibilities of shorter duration may or may not have been recorded. For the purposes of this report, it is assumed that if the visibility is reported as being reduced by dust at a given three hourly observation then that condition lasted at least 1 hour, ergo, a duration factor of 1.00 for blowing dust and dust storms lasting at least 1 hour.

Less Than 3.7 Days Per Year with Blowing Dust

Of the original 651 stations for which the ETAC provided data, 257 stations were not included in Parts I, II, and III and were not among those 45 stations of Part IV which were characterized by more than 3.7 days per year with blowing dust and a period of record of 5 years or more. These stations are listed alphabetically by country in Table 4. Included in the listing are period of record, WMO number, latitude, longitude, elevation, and annual number of days with blowing dust and dust storm.

SUMMARY

For the 45 stations covered, the patterns of occurrence are similar with the highest frequency of occurrence being centered in the late afternoon in spring and early summer. The period of record is not identical for all stations; therefore, caution is urged where comparisons between or among stations is required.

Avg	*	*	*	*	*	*	*	*	*	*	*	*	24

N = Arithmetic mean of the annual number of occurrences of dust equal to or greater than 1-hour duration.

*<0.5%

Likelihood (%) of a visibility condition lasting for a certain period of time at a specified hour and month equals duration factor times diurnal variation by month.
